ABSTRACT: We derive WKB expressions for glueball masses of various finite temperature supergravity models. The results are very close to recent numerical computations. We argue that the spectra has some universality that depends only on the dimension of the AdS space and the singularity structure of the horizon. This explains the stability of the 0^{++} glueball mass ratios between various models. We also consider the recently proposed nonsupersymmetric model arising from the type 0 string. In the supergravity limit of this model, the heavy quark potential has an effective coupling with $1/(\log u)$ behavior in the UV . Unfortunately, the supergravity solution implies that the heavy quark potential is still coulombic in the infrared, with an effective coupling of order 1. We also argue that the type 0 supergravity background solution does not have normalizable glueball solutions.

1. Introduction

One of the many interesting developments to arise out of Maldacena's conjecture [1, 2, 3] is the ability to study nonsupersymmetric large N gauge theories at strong coupling [4, 5, 6, 7, 8, 9]. One studies a d dimensional euclidean gauge theory at finite temperature, which is equivalent to a theory with $d - 1$ noncompact directions and a Euclidean time compactified on a circle of circumference β . As was pointed out by Witten [4] the Maldacena conjecture relates wave equations in an AdS blackhole background to two point correlation functions of a finite temperature Yang-Mills gauge theory.

Using this conjecture Witten argued that the dilaton wave equation in this background implies a discrete glueball spectrum with a finite gap. This spectrum was studied more closely in [9] and also in [10, 11] where comparisons were made between the supergravity results and lattice gauge theory results. However, the strong coupling behavior of QCD is highly nonuniversal, so there really is no reason to expect much similarity between the lattice results and the supergravity results, beyond the fact that the spectra for both theories is discrete with a finite gap.

However, one might hope to find some universality within different supergravity models. In particular, other supergravity models were recently studied that correspond to finite temperature QCD with its R symmetry group broken [12, 13]. This has the nice feature of getting rid of some of the unwanted Kaluza-Klein states. It was noted in [13] that there seemed to be some universality in the mass ratios of $J^{PC} = 0^{++}$ glueball states for the different supergravity models. One of the purposes of this paper is to explain this universality by finding WKB approximations for the glueball spectra. As it turns out, the leading order term depends on the particular

supergravity theory being considered. However, the subleading term has universal behavior, depending only on the dimension of the AdS space and the horizon singularity. One could then speculate that if “real” QCD has a supergravity dual that is asymptotically AdS_n , then it too will have some universal behavior, that depends only on n and the singularity structure at a horizon.

In all of the above models, supersymmetry was broken by turning on a temperature. Therefore, supersymmetry is restored in the ultraviolet and hence the supergravity solutions do not exhibit asymptotic freedom. Recently, a nonsupersymmetric gauge model was proposed that arises from D3 branes in the nonsupersymmetric type 0 theory [14]. Since supersymmetry is never restored, one should expect to see running of the coupling in the UV . In principle, one could also apply the WKB analysis to this model and derive its glueball spectrum, up to an overall scale.

The type 0 theory has a tachyon in the bulk that presumably gets an expectation value. The authors in [14] derived a supergravity action for this model. We will find asymptotic solutions to the equations of motion coming from this supergravity action. The results found here should be taken with a grain of salt since the background metric has curvature that is either greater than or roughly equal to the string scale in both the UV and IR . Nonetheless, one still hopes that the supergravity results are qualitatively correct, as in the case for the entropy of $\mathcal{N} = 4$ super Yang-Mills at finite temperature, where the supergravity result differed from the perturbative Yang-Mills result by a factor of $3/4$ [15]. In fact, in the type 0 case we do find a running of the effective coupling in the UV . However, in the infrared we do not find confinement nor do we find normalizable glueball solutions. This suggests that one must consider the full σ -model to see such behavior.

In section 2 we derive WKB expressions for the masses of 0^{++} in the finite temperature models described in [4]. We compare these results to the recent numerical results and we find excellent agreement. We also describe the six dimensional model with five uncompactified directions and argue that the glueball spectrum has a finite gap with a continuous spectrum above the gap.

In section 3 we derive WKB expressions for more general supergravity models, and we show that these expressions have a general form that depends on the dimension of the asymptotic AdS space and the singularity at the horizon. This explains the recently noted stability of the spectrum for the class of models discussed in [13]. Using this analysis we also find WKB expressions for the 0^{--} and 0^{-+} glueballs in 3 and 4 dimensions respectively. We again find good agreement with the numerical results.

In section 4 we describe our findings for the type 0 model. We derive expressions for the metric and the coupling in the ultraviolet and infrared and use this to find the heavy quark potential in these two limits. We also argue that the IR behavior of the metric and coupling does not allow for normalizable glueball solutions.

In section 5 we present our conclusions.

2. WKB Masses for 0^{++} Glueballs

In this section we compute masses using a WKB approximation for the 0^{++} glueballs in the supergravity models in [4]. In the next section we will consider more general cases as well as the WKB solutions for the other glueballs recently discussed in the literature.

The 0^{++} glueball spectrum is governed by the dilaton wave equation in the appropriate background. Consider first the background arising from N stationary Dp branes at finite temperature T . The metric in the near horizon limit is

$$ds^2 = \alpha' \left[\frac{U^{(7-p)/2}}{\sqrt{gN}} \left(\left(1 - \left(\frac{U_T}{U} \right)^{7-p} \right) dt^2 + dx_i^2 \right) + \frac{\sqrt{gN}}{U^{(7-p)/2}} \left(\frac{dU^2}{1 - \left(\frac{U_T}{U} \right)^{7-p}} + U^2 d\Omega_{8-p}^2 \right) \right], \quad (2.1)$$

and with a dilaton background

$$e^\phi = g \left(\frac{U^{7-p}}{gN} \right)^{(p-3)/4}. \quad (2.2)$$

The temperature T is related to U_T and the coupling by

$$T = \frac{7-p}{4\pi} \frac{U_T^{(5-p)/2}}{\sqrt{gN}}. \quad (2.3)$$

The dilaton equation of motion is

$$\partial_\mu e^{-2\phi} \sqrt{g} g^{\mu\nu} \partial_\nu \phi = 0. \quad (2.4)$$

Assuming that ϕ is of the form $\phi = e^{ik \cdot x} \rho(u)$ with $k^2 = -M^2$, (2.4) reduces to

$$\partial_U \left(U^{7-p} - U_T^{7-p} \right) U \partial_U \phi + M^2 g N U \phi = 0. \quad (2.5)$$

Defining a new variable $x = U^2/U_T^2$ and rescaling, (2.5) reduces further to

$$\partial(x^{2+1/n} - x) \partial \phi + \lambda \phi = 0, \quad (2.6)$$

where $n = 2/(5-p)$ and

$$\lambda = M^2 \left(\frac{n+1}{4\pi n T} \right)^2. \quad (2.7)$$

The differential equation in (2.6) has singularities at $x = 0, \infty$ and at all $1/(1+n)$ roots of unity, so solutions to this equation are unknown for finite n . In order to do the WKB approximation, we define a new function $\psi = \sqrt{\frac{x-1}{x^{2+1/n}-x}} \phi$, and we change variables to $x = 1 + e^y$. The equation in (2.6) now takes the form

$$\psi'' + \left(\frac{\lambda}{f} e^y - \frac{1}{2} \frac{f''}{f} + \frac{1}{4} \left(\frac{f'}{f} \right)^2 \right) \psi = 0, \quad (2.8)$$

where the primes denote derivatives with respect to y and $f = (1+e^{-y})((e^y+1)^{1+1/n}-1)$.

For large negative y , the term in front of ψ in (2.8) is approximately

$$\frac{\lambda}{f}e^y - \frac{1}{2}\frac{f''}{f} + \frac{1}{4}\left(\frac{f'}{f}\right)^2 \approx \left(\frac{\lambda n}{1+n} - \frac{1}{4}(2+1/n)\right)e^y \quad y \ll 0. \quad (2.9)$$

For large positive y the asymptotic behavior for this term is

$$\frac{\lambda}{f}e^y - \frac{1}{2}\frac{f''}{f} + \frac{1}{4}\left(\frac{f'}{f}\right)^2 \approx \lambda e^{-y/n} - \frac{(n+1)^2}{4n^2} \quad y \gg 0. \quad (2.10)$$

Thus, for λ sufficiently large there will be two turning points at $y = -\infty$ and $y = y_0$, where

$$y_0 \approx n \log(4n\lambda/(n+1)^2). \quad (2.11)$$

Hence, the WKB approximation for this curve gives

$$(m+1/2)\pi = \int_{-\infty}^{y_0} dy \sqrt{\frac{\lambda}{f}e^y - \frac{1}{2}\frac{f''}{f} + \frac{1}{4}\left(\frac{f'}{f}\right)^2}, \quad m \geq 0. \quad (2.12)$$

To leading order in M we may approximate the WKB integral as

$$\int_{-\infty}^{\infty} dy \sqrt{\lambda} e^{y/2} f^{-1/2} = \int_1^{\infty} dx \frac{\sqrt{\lambda}}{\sqrt{x^{2+1/n}-x}} = \frac{M}{T} \frac{\Gamma\left(\frac{1}{2+2n}\right)}{4\pi^{1/2}\Gamma\left(\frac{2+n}{2+2n}\right)}. \quad (2.13)$$

Let us now consider the next order term in the $1/M$ expansion of (2.12). There are two contributions to this constant piece. There is one contribution because (2.13) was integrated to ∞ instead of y_0 . Hence we should subtract from (2.13) the term

$$\int_{y_0}^{\infty} dy \sqrt{\frac{\lambda e^y}{f}} = (n+1) + O(1/\sqrt{\lambda}). \quad (2.14)$$

The other contribution comes from integrating the integrand in (2.12) near y_0 . Subtracting off the leading order term, this contribution is given by

$$\begin{aligned} \int_{-\infty}^{y_0} dy \sqrt{\frac{\lambda}{f}e^y - \frac{1}{2}\frac{f''}{f} + \frac{1}{4}\left(\frac{f'}{f}\right)^2} - \sqrt{\frac{\lambda e^y}{f}} &\approx \\ &\approx \int_1^{e^{y_0}} \frac{dx}{x^{1+1/(2n)}} \left(\sqrt{\lambda - \frac{(1+1/n)^2}{4}x^{1/n}} - \sqrt{\lambda} \right) \\ &= \left(1 - \frac{\pi}{2}\right)(n+1) + O(1/\sqrt{\lambda}). \end{aligned} \quad (2.15)$$

We have used the fact that f''/f and f'/f are almost constant near the turning point $y = y_0$ for large $\sqrt{\lambda}$. Hence, using (2.7), (2.13), (2.14) and (2.15) in (2.12), we find that

$$M^2 = 16\pi^3 \left(\frac{\Gamma\left(\frac{2+n}{2+2n}\right)}{\Gamma\left(\frac{1}{2+2n}\right)} \right)^2 T^2 m(m+n) + O(m^0), \quad m \geq 1. \quad (2.16)$$

In the QCD_3 case, $n = 1$ and hence the mass relation is

$$M^2 = 8\pi \left(\Gamma\left(\frac{3}{4}\right) \right)^4 T^2 m(m+1) + O(m^0), \quad m \geq 1, \\ \approx 5.74216 (\pi T)^2 m(m+1). \quad (2.17)$$

We have factored out a π^2 term in the second line of (2.17) to match the units used in [9]. Table 1 compares the WKB expressions with the numerical results found in [9] and we see that the agreement is very close.¹

In the case of QCD_4 , we have $n = 2$ and hence the WKB relation

$$M = 4\pi^{3/2} \frac{\Gamma\left(\frac{2}{3}\right)}{\Gamma\left(\frac{1}{6}\right)} T \sqrt{m(m+2)} + O(m^{-1}), \quad m \geq 1. \quad (2.18)$$

Table 2 compares the WKB results in (2.18) to the numerical results of [16]. Again, we find that the WKB result quickly approaches the numerical eigenvalues.

We conclude this section by examining the behavior of the mass spectrum in the limit $n \rightarrow \infty$. Taking this limit we approach $p = 5$, corresponding to six dimensional euclidean QCD with a compactified direction. In the large n limit, the mass equation in (2.16) reduces to

$$M^2 = 4\pi^4 T^2 \left(C + \frac{m}{n} \right), \quad m \geq 1, \quad (2.19)$$

where C is a constant to be determined. Thus, it appears that for nonzero C there is a finite gap in the spectrum, but above this gap the spectrum is continuous. We can see this more clearly by taking $n \rightarrow \infty$ limit in (2.6). In this case (2.6) reduces to Legendre's equation and so the solutions that are regular at $x = 1$ are $P_\ell(2x-1)$ where $\lambda = -\ell(\ell+1)$. If $\lambda \leq 1/4$ then $P_\ell(2x-1)$ is not normalizable at infinity. If $\lambda > 1/4$, then $P_\ell(2x-1)$ is plane wave normalizable. Therefore, we find that the constant in (2.19) is $C = \pi^{-2}$ and thus there is a gap. This unusual behavior for the six dimensional theory is probably related to its nonlocal nature [17, 18].

¹In [9] a WKB expression was given with a numerical factor of 6.

3. Glueball masses for generalized supergravity backgrounds

In the previous section we have seen that the analytic WKB expressions give accurate results for the eigenvalues of the dilaton wave equation. This strengthens our confidence in the procedure, and encourages us to use it in more general situations.

In this section we discuss the WKB approximation for 0^{++} glueballs in more general supergravity backgrounds. We will argue that there is universality in the spectra which only depends on the dimensionality of the AdS space at infinity and the singularity structure at the horizon. Using results derived here we can find WKB approximations for 0^{-+} glueballs in QCD_4 and 0^{--} glueballs in QCD_3 . We can also explain the stability of the 0^{++} spectrum for models coming from rotating branes [13], and the change in the spectrum for the 0^{-+} glueballs in these same models.

The only assumptions that we make are that there are angular independent solutions to the dilaton wave equation in (2.4) and that for large U the metric approaches an AdS solution. In this case, we can reduce (2.4) to

$$\partial_U (f(U) \partial_U \phi) + M^2 h(U) = 0, \quad (3.1)$$

where

$$f(U) = \sqrt{g} e^{-2\phi} g^{UU}, \quad h(U) = \sqrt{g} e^{-2\phi} g^{xx}. \quad (3.2)$$

Let us suppose that there is a U_0 such that near $U = U_0$,

$$f(U) \sim (U - U_0)^s, \quad h(U) \sim (U - U_0)^q. \quad (3.3)$$

The assumption that asymptotically the solution is AdS implies that $f(U) \sim U^{8-p}$ and $h(U) \sim U$ if $U \gg U_0$.

Let us define $e^y = U - U_0$, $\tilde{f}(y) = f(e^y + U_0) e^{sy}$ and $\tilde{h}(y) = h(e^y + U_0) e^{qy}$. If we let $\phi = \frac{e^{(1-s)y/2}}{\sqrt{\tilde{f}}} \psi$, then (3.1) becomes

$$\partial_y^2 \psi + V(y) \psi = 0, \quad (3.4)$$

where

$$V(y) = M^2 e^{(q+2-s)y} \frac{\tilde{h}(y)}{\tilde{f}(y)} + \frac{1}{4} \left(\frac{\partial_y (e^{(s-1)y} \tilde{f}(y))}{e^{(s-1)y} \tilde{f}(y)} \right)^2 - \frac{1}{2} \frac{\partial_y^2 (e^{(s-1)y} \tilde{f}(y))}{e^{(s-1)y} \tilde{f}(y)}. \quad (3.5)$$

For large negative and positive y we have

$$\begin{aligned} V(y) &\approx C_1 M^2 e^{(q+2-s)y} - \frac{1}{4} (s-1)^2 & y \ll 0, \\ V(y) &\approx C_2 M^2 e^{(p-5)y} - \frac{1}{4} (7-p)^2 & y \gg 0, \end{aligned} \quad (3.6)$$

where C_1 and C_2 are unimportant constants for this discussion. Hence, we find two turning points which for large enough M can be approximated as

$$\begin{aligned} y_1 &\approx -\frac{1}{q+s-2} \log \left(\frac{4C_1 M^2}{(s-1)^2} \right), \\ y_2 &\approx \frac{1}{5-p} \log \left(\frac{4C_2 M^2}{(7-p)^2} \right). \end{aligned} \quad (3.7)$$

The WKB approximation is then

$$\left(m + \frac{1}{2}\right) \pi = \int_{y_1}^{y_2} dy \sqrt{V(y)}. \quad (3.8)$$

The leading order contribution to the integral in (3.8) is

$$M\xi = M \int_{-\infty}^{+\infty} dy e^y \sqrt{\frac{e^{qy} \tilde{h}(y)}{e^{sy} \tilde{f}(y)}} = M \int_{U_0}^{\infty} dU \sqrt{\frac{g^{xx}}{g^{UU}}}, \quad (3.9)$$

where we have used (3.2). It is clear that (3.9) sets the inverse mass scale for the glueballs. We can compare this to the scale coming from the heavy quark potentials. In this latter case, the string tension along the brane, as a function of the energy scale U is

$$\sigma(U) = \frac{1}{2\pi} g_{xx}(U) \quad (3.10)$$

and at large quark separation the string tension approaches $\frac{1}{2\pi} g_{xx}(U_0)$. Hence we can rewrite (3.9) as

$$M\xi = M \int_{U_0}^{\infty} dU \sqrt{g_{UU}} (2\pi\sigma(U))^{-1/2}. \quad (3.11)$$

In other words, the inverse mass scale is a one-loop integral of the square root of the inverse tension integrated over all energy scales with a measure $\sqrt{g_{UU}}$.

Let us now consider the next to leading order corrections. The computations are similar to those in (2.14) and (2.15). Using (3.6), the correction coming from the turning point at $y = y_2$ is

$$\begin{aligned} & -\sqrt{M^2 C_2} \int_{y_2}^{\infty} dy e^{(p-5)y/2} + \\ & + \int_{-\infty}^{y_2} dy \left(\sqrt{M^2 C_2 e^{(p-5)y} - \frac{1}{4}(7-p)^2} - \sqrt{M^2 C_2} e^{(p-5)y/2} \right) = -\left(\frac{7-p}{5-p}\right) \frac{\pi}{2}, \end{aligned} \quad (3.12)$$

while the correction coming from the turning point at $y = y_1$ is

$$\begin{aligned} & -\sqrt{M^2 C_1} \int_{-\infty}^{y_2} dy e^{(q+2-s)y/2} + \\ & + \int_{y_2}^{+\infty} dy \left(\sqrt{M^2 C_1 e^{(q+2-s)y} - \frac{1}{4}(s-1)^2} - \sqrt{M^2 C_2} e^{(q+2-s)y/2} \right) = -\frac{|s-1|}{q+2-s} \frac{\pi}{2}. \end{aligned} \quad (3.13)$$

Putting everything together, we find that the WKB masses are

$$M^2 = \frac{\pi^2}{\xi^2} m \left(m + \frac{2}{5-p} + \frac{|s-1|}{q+2-s} \right) + \mathcal{O}(m^0), \quad m \geq 1. \quad (3.14)$$

By assuming that the supergravity solution is asymptotically *AdS*, we have chosen a particular singularity structure for the point at spatial infinity. The basic arguments used here are still applicable even if the solution is not *AdS*, so long as the singularity structure at infinity is known.

We now consider some of the examples discussed in the recent literature. For the case of rotating nonextremal D4 branes considered in [12, 13], the dilaton wave equation reduces to

$$\partial_u \left[u \left(u^6 - (4gN)^2 a^4 u^2 - u_T^6 \right) \partial_u \phi \right] + 4gN M^2 u^3 \phi = 0, \quad (3.15)$$

where a parameterizes the angular momentum, and we have replaced U with $u^2 = U$, to match the form of the equation in [13]. If $a = 0$ this reduces to the nonrotating D4 brane equation in (2.5). The horizon occurs at $u = u_0$ with

$$u_0^6 - a^4 u_0^2 - u_T^6 = 0. \quad (3.16)$$

Hence, it is clear that (3.15) has the form of (3.1) and (3.3), with $s = 1, q = 0$, for *all* values of a . Therefore, we find that the WKB expression for the masses is

$$M^2 = m(m+2) \frac{\pi^2}{4gN} \left[\int_{u_0}^{\infty} du \frac{u}{\sqrt{u^6 - (4gN)^2 a^4 u^2 - u_T^6}} \right]^{-2}, \quad m \geq 1. \quad (3.17)$$

Since the singularity structure does not change when a is varied, we see that the WKB mass ratios do not change either. Thus, we see the reason for the stability of the glueball masses observed in [13]. This might also explain why supergravity glueball results are reasonably close to lattice results.

We can compute the integral in (3.17) exactly in the two limits $a = 0, \infty$. The result for $a = 0$ is in (2.18). For large a we find

$$M^2 = \frac{8}{\pi} \left(\Gamma \left(\frac{3}{4} \right) \right)^4 a^2 m(m+2), \quad m \geq 1. \quad (3.18)$$

The next examples are the 0^{-+} glueball masses for the rotating nonextremal D4 branes. In this case, the equation of motion for one of the angular components of the R-R 1-form field is [13]

$$\partial_u \left[u^3 (u^4 - (4gN)^2 a^4) \partial_u \chi \right] + 4gN M^2 \frac{u^5 (u^4 - (4gN)^2 a^4)}{u^6 - (4gN)^2 a^4 u^2 - u_T^6} \chi = 0. \quad (3.19)$$

This equation also has the same form as (3.1), but with $s = 0$ and $q = -1$ for generic a . Therefore, using (3.14) we find

$$M^2 = m(m+3) \frac{\pi^2}{4gN} \left[\int_{u_0}^{\infty} du \frac{u}{\sqrt{u^6 - (4gN)^2 a^4 u^2 - u_T^6}} \right]^{-2}, \quad m \geq 1, \quad (3.20)$$

for the 0^{-+} masses. In the $a = 0$ limit this reduces to

$$M = 4\pi^{3/2} \frac{\Gamma\left(\frac{2}{3}\right)}{\Gamma\left(\frac{1}{6}\right)} T \sqrt{m(m+3)}, \quad m \geq 1. \quad (3.21)$$

Table 3 shows a comparison of the WKB masses to the numerical results in [16]. The WKB result for the mass ratio between the lowest level 0^{-+} and 0^{++} states is $M_{-+}/M_{++} = 2/\sqrt{3} \approx 1.155$ which is reasonably close to the numerical result. In fact the difference between the WKB and numerical results is smaller than present day lattice errors.

However, in the limit that $a \rightarrow \infty$, the WKB structure will change for the 0^{-+} states. This is because the singularity structure of (3.19) changes. In fact, in the large a limit we end up with the same equation as the dilaton. Hence we find the same WKB masses. The only difference is that we have to discard the lowest eigenvalue [13]. Hence the WKB mass ratio in the large a limit is $\frac{M_{-+}}{M_{++}} = \sqrt{8/3} \approx 1.63$. This is again close to the numerical result of 1.59 and it is also close to the lattice result of $1.61 \pm .19$.

Our final example is the WKB spectrum for the O^{--} glueballs in QCD_3 . After a rescaling of the NS-NS 2 form field, the relevant component satisfies the wave equation [9]

$$\partial_U \left[U^5 (U^4 - U_T^4) \partial_U \chi \right] + g N M^2 U^5 \chi = 0. \quad (3.22)$$

This does not have quite the same form as (3.1) because of the extra U^4 term, but the WKB analysis is almost identical and results in the spectrum

$$M = \sqrt{8\pi} \left(\Gamma\left(\frac{3}{4}\right) \right)^2 T \sqrt{m(m+3)}, \quad m \geq 1. \quad (3.23)$$

Table 4 is a comparison of the WKB and numerical results [10]. Again, we find close agreement. Finally, the WKB mass ratio for the lightest states with 0^{--} and 0^{++} quantum numbers is $\frac{M_{--}}{M_{++}} = \sqrt{2}$.

4. The type 0 nonsupersymmetric model.

In this section we make some general statements about the type 0 model [19, 20] recently discussed in [14]. We find asymptotic solutions for the lowest order supergravity approximation. We find a running of the effective coupling, but no confining behavior and no normalizable glueball solutions.

The type 0 model has a closed string tachyon, no fermions and a doubled set of R-R fields. In particular, there is no longer a self dual constraint on the 5-form field strength. Since the number of R-R fields is doubled, so are the number of D brane types [21]. Hence one can have D3 branes that are electric instead of dyonic. If we have N parallel electric D3 branes, then the low energy effective action on the branes is thought to be $SU(N)$ QCD with adjoint scalar fields, but no fermions. Hence, there is no supersymmetry and the coupling will run. There is no open string tachyon [21], so there is no tachyon in this QCD model.

The authors in [14] argued that the *closed* string tachyon can get an expectation value, and that its mass squared gets a positive shift from the background 5 form flux. The background tachyon field acts as a source for the dilaton, so the dilaton is no longer constant. One then makes the following ansatz for the metric [14]

$$ds^2 = e^{\frac{1}{2}\phi} \left(e^{\frac{1}{2}\xi - 5\eta} d\rho^2 + e^{-\frac{1}{2}\xi} dx_{||}^2 + e^{\frac{1}{2}\xi - \eta} d\Omega_5^2 \right), \quad (4.1)$$

where ϕ , ξ and η are functions of ρ only. The equations of motion then reduce to a Toda like system with an action [14]²

$$S = \int d\rho \left[\frac{1}{2}\dot{\phi}^2 + \frac{1}{2}\dot{\xi}^2 + \frac{1}{4}\dot{T}^2 - 5\dot{\eta}^2 - V(\phi, \xi, \eta, T) \right],$$

$$V(\phi, \xi, \eta, T) = \frac{1}{2}T^2 e^{\frac{1}{2}\phi + \frac{1}{2}\xi - 5\eta} + 20e^{-4\eta} - Q^2 f^{-1}(T) e^{-2\xi}, \quad (4.2)$$

and a constraint

$$\frac{1}{2}\dot{\phi}^2 + \frac{1}{2}\dot{\xi}^2 + \frac{1}{4}\dot{T}^2 - 5\dot{\eta}^2 + V(\phi, \xi, \eta) = 0. \quad (4.3)$$

Q is the total D3 brane charge which is proportional to N , T is the tachyon field and $f(T)$ is a function given by [14]

$$f(T) = 1 + T + \frac{1}{2}T^2 + O(T^3). \quad (4.4)$$

For large Q , the tachyon expectation value is determined by setting $f'(T) = 0$. As a first approximation, we may assume that the tachyon is constant as a function of ρ .

If $T = 0$ then the solution reduces to the $\mathcal{N} = 4$ solution. When T is nonzero, then all fields are coupled and there is no known analytic solution. However, we can attempt to find approximate solutions that are valid in the UV and IR regions. In the UV , we expect the dilaton field to be relatively constant, at least compared with ξ and η . Assuming that ϕ is constant and thus ignoring its kinetic term, the equations for ξ and η can be solved exactly, at least in the near horizon limit. In this case we find

$$e^\xi = C_1 \rho, \quad e^\eta = C_2 \rho^{1/2},$$

²We are using units where $\alpha' = 1$.

$$\begin{aligned}\frac{1}{4}T^2 e^{\frac{1}{2}\phi} \frac{C_1^{1/2}}{C_2^5} + \frac{2Q^2}{C_1^2 f(T)} - 1 &= 0, \\ \frac{5}{2}T^2 e^{\frac{1}{2}\phi} \frac{C_1^{1/2}}{C_2^5} + \frac{80}{C_2^4} - 5 &= 0.\end{aligned}\tag{4.5}$$

One can easily check that this satisfies the constraint equation in (4.3). If we plug this back into the metric, we find that the solution is still $AdS_5 \times S_5$, but the curvatures of the two spaces no longer match, S_5 now has smaller curvature than AdS_5 . In this case the Ricci scalar for the total space is proportional to

$$R \sim T^2 e^{\frac{1}{2}\phi}.\tag{4.6}$$

Using the ξ and η solutions as inputs, we can go back and find an approximate solution for ϕ in terms of ρ . Using the ansatz $e^{\frac{1}{2}\phi} = C_0(\log \rho)^\alpha$, and plugging this into the equation of motion for ϕ

$$\ddot{\phi} + \frac{1}{4}T^2 e^{\frac{1}{2}\phi + \frac{1}{2}\xi - 5\eta} = 0,\tag{4.7}$$

we find that the ansatz is a leading order solution if $\alpha = -1$ and $C_0 = -8C_2^5/(T^2\sqrt{C_1})$. Setting $\rho = u^{-4}$, and using the lowest order solutions for C_1 and C_2 from (4.5), we learn that the leading order behavior for the coupling is

$$e^{-\phi} = \frac{1}{g_{YM}^2} = \frac{QT^4(\log u)^2}{4096\sqrt{2f(T)}}.\tag{4.8}$$

Thus we find a running coupling, but instead of a linear log dependence, the coupling runs with a log squared! One can easily check that to leading order in $1/\log u$, the constraint equation is still satisfied. We can also estimate the range of validity for this solution. Computing the leading order corrections to C_1 and C_2 , one finds that

$$C_1 = \frac{2Q}{\sqrt{2f(T)}} \left(1 + \frac{1}{4\log u}\right), \quad C_2 = 2 \left(1 + \frac{1}{4\log u}\right).\tag{4.9}$$

We can also compare the terms in the potential that depend on the tachyon. Since

$$\frac{1}{4}T^2 e^{\frac{1}{2}\phi + \frac{1}{2}\xi - 5\eta} \sim \frac{u^8}{2\log u}, \quad Q^2 f^{-1}(T) e^{-2\xi} \sim \frac{u^8}{2},\tag{4.10}$$

our solution with a constant T with $f'(T) = 0$ is valid so long as $\log u \gg 1$.

The metric in the large u limit is

$$ds^2 = \frac{32}{T^2 \log u} \left(\frac{du^2}{u^2} + \frac{\sqrt{2f(T)}}{2Q} \left(1 + \frac{1}{\log u}\right) r^2 dx_{||}^2 + \left(1 + \frac{1}{\log u}\right) d\Omega_5^2 \right).\tag{4.11}$$

Hence we can trust the supergravity solution only if $T \ll 1$, since $\log u \gg 1$. However, it is clear that $T \sim 1$ if $f'(T) = 0$, hence one should not expect the

supergravity result to be particularly trustworthy. Indeed, we have found that while the supergravity computation results in a coupling running to zero, it runs with the wrong power of $\log u$.

Nevertheless, the effective coupling between a heavy quark and its antiquark *does* appear with the expected \log dependence. Using the Wilson line computation of [22, 23], one finds that quark potential is given by

$$V \approx -\frac{256 \pi^3}{\Gamma(\frac{1}{4})^4 T^2 L \log(L_0/L)}, \quad L \ll L_0, \quad (4.12)$$

where we have plugged $R^2 = \frac{32}{T^2 \log u}$ into the expressions derived in [22, 23]. L_0 is some length of order the string scale. Recall that the $\mathcal{N} = 4$ potential comes with a coefficient \sqrt{gN} . It is this coefficient, and not the 't Hooft-Polyakov tension gN , that plays the role of $1/\alpha'$ for the supergravity models. For a string theory with extrinsic curvature, the string tension has a $(\log u)^{-1}$ dependence [24, 25]. Hence our result is in line with rigid string results, so long as one remembers that the tension is \sqrt{gN} .

Even though we cannot really trust the supergravity solution for large u , we might be able to trust it for small u . However, here we will see that the situation is even worse. In particular, we will find that the dilaton wave equation in the lowest order supergravity background has no normalizable glueball solutions. Moreover, the heavy quark potential is *not* confining.

In order to study the IR behavior, let us follow the suggestion of [14] and search for solutions for the toda system assuming that the second term in V is small compared to the other terms. This corresponds to a small curvature for the S_5 . Dropping this second term in V and assuming a constant T , one can now find an exact solution to the equations of motion that satisfies the constraint. The solution is

$$e^\phi = C_0^2 \rho^{5/9}, \quad e^\eta = C_2 \rho^{5/9}, \quad e^\xi = \frac{3Q}{\sqrt{2f(T)}} \rho, \quad (4.13)$$

with the relation

$$20(2f(T))^{1/4} C_2^5 - 9T^2 \sqrt{3Q} C_0 = 0. \quad (4.14)$$

Comparing all terms in V , one has $e^{\frac{1}{2}\phi + \frac{1}{2}\xi - 5\eta} \sim \rho^{-2}$, $e^{-2\xi} \sim \rho^{-2}$, but $e^{-4\eta} \sim \rho^{-20/9}$. Hence this solution is valid for large ρ . From (4.13), the coupling blows up as $\rho \rightarrow \infty$ and after substituting $\rho = 1/u^4$ the metric is

$$ds^2 = \frac{20}{9T^2} \left(16 \frac{du^2}{u^2} + \frac{C_2^5 \sqrt{2f(T)}}{3Q} u^{8/9} dx_{||}^2 + C_2^5 u^{-8/9} d\Omega_5^2 \right). \quad (4.15)$$

C_2 remains as a leftover integration constant.

In the small u limit, the T dependent terms in the potential are now comparable, so the tachyon expectation value is no longer at $f'(T) = 0$. Instead, plugging in the

solution of (4.13) and (4.14) into the tachyon equation of motion, one finds that $\ddot{T} = 0$ if

$$10f(T) + Tf'(T) = 0. \quad (4.16)$$

Using the function in (4.4) for $f(T)$, one finds that there are no real solutions of (4.16) for T . However, if we were to include the cubic term in $f(T)$ or include the quartic term $c_1 T^4$ in the action, then a real solution would exist.

As in the UV , the curvature in the IR is small if $T \ll 1$. However, we expect solutions to (4.16) to be $T \sim 1$. The curvature is now at the string scale, so we cannot truly trust the supergravity solution in this limit either.

We can attempt to find glueball solutions. Using the asymptotic expressions in the dilaton equation of motion we find the equations

$$\begin{aligned} \partial_u \left[u^5 \partial_u \phi \right] + \frac{2Q M^2}{\sqrt{2f(T)}} u \phi &= 0, & u \gg 1, \\ \partial_u \left[u^5 \partial_u \phi \right] + \frac{48Q M^2}{C_2^5 \sqrt{2f(T)}} u^{21/9} \phi &= 0, & u \ll 1. \end{aligned} \quad (4.17)$$

For large u , we see that the dilaton equation of motion reduces to the $\mathcal{N} = 4$ result. It appears that the only other singularity is at $u = 0$. Using the arguments of the previous section, one learns from (4.17) that this singularity has $s - q = 5 - 21/9 > 2$, hence no glueball solutions are possible.

We can also easily see that the potential between the heavy quarks does not confine for these solutions. If we define a new variable v such that

$$v = \frac{1}{9} \left(\frac{\sqrt{2f(T)}}{3Q} \right)^{1/2} u^{4/9}, \quad (4.18)$$

then the metric in (4.15) is

$$ds^2 = \frac{180}{T^2} \left(\frac{dv^2}{v^2} + v^2 dx_{||}^2 + \frac{(C_2/3)^{10} \sqrt{2f(T)}}{Q^2 v^2} d\Omega_5^2 \right). \quad (4.19)$$

From this metric, we see that $R^2 = \frac{180}{T^2}$, and so the heavy quark potential is

$$V \approx -\frac{1440 \pi^3}{\Gamma(\frac{1}{4})^4 T^2 L}, \quad L \gg L_0. \quad (4.20)$$

Hence, the supergravity result implies that the effective heavy quark coupling increases when going from the UV to the IR , but the quark potential does not develop a linear term and remains coulombic.

We could certainly generate a linear quark potential by going to finite temperature since the supergravity background would now have a horizon at finite u . The

down side of this scenario is that the the theory will essentially be reduced to QCD in three dimensions.

In the end one probably has to consider the full σ -model in order to get a linear quark potential and normalizable glueball solutions. At the very least, one could try including the $\alpha'^3 R^4$ terms in the action to see if this would qualitatively change the behavior in the infrared. Perhaps one could then combine the UV results found here with IR results derived from the σ -model to say something concrete about the WKB glueball masses.

5. Conclusions

We have seen from the WKB mass expressions that there is some degree of universality for glueball mass ratios between different supergravity models. In the examples where the ratios change, the behavior can be attributed to a change of the singularity structure at the horizon.

The finite temperature models do not exhibit a running of the coupling in the UV . However, we have shown that the type 0 model has the desired behavior. Unfortunately, it does not appear to be confining in the IR . Hopefully confinement will appear in the solution for the full σ -model. Or perhaps a model can be found that combines the desired features of the nonsupersymmetric models discussed here.

Acknowledgments

I would like to thank O. Bergman, E. Gimon, P. Horava and D. Minic for discussions. This work was supported in part by funds provided by the DOE under grant number DE-FG03-92-ER40701.
